

Brain Extraction/Segmentation

Overall Pipeline

Brain Extraction 3 Different Attempts

In this tutorial we will discuss performing brain segmentation using:

- the brain extraction tool (BET) (Smith 2002) in `FSL` (Jenkinson et al. 2012)
 - without bias correction (method 1) and with (method 2)
- a multi-atlas approach, called “multi-atlas label fusion” with the `mal_f` command (method 3).
- (extra slides) a robust version using a wrapper function in `extrantsr`, `fslbet_robust`

MS Lesion T1

Let's reset and read in the T1 image from a MS lesion data set:

```
library(neurobase)
t1_fname = "training01_01_mprage.nii.gz"
t1 = neurobase::readnii(t1_fname)
rt1 = robust_window(t1);
red0.5 = scales::alpha("red", 0.5) # for plotting later
```

T1-weighted T1 Image

ortho2 (rt1)

Attempt 1: Brain Extraction of T1 image using BET

Here we will use FSL's Brain Extraction Tool (BET) to extract the brain tissue from the rest of the image (general overview):

- 2nd and 98th percentiles are calculated. $(98\text{th} - 2\text{nd}) * 10\% + 2\text{nd percentile}$ used to threshold out background
- From non-thresholded voxels - calculate center of gravity (COG)
- Calculate radius of brain and median intensity of all points within "spherical brain" (used in last step)
- Perform region growing and iterating to get brain surface
- Smooth surface
- Use median intensity to shrink surface to the "real" surface

Attempt 1: Brain Extraction of T1 image using BET

`fslr` - wraps FSL commands to use in R - registration, image manipulation

`fslr::fslbet` - takes in a filename/nifti and calls FSL `bet` function - additional options can be passed to FSL command in using `opts`

```
library(fslr)
ss = fslbet(infile = t1_fname)
```

FSL BET Results - Missing Brain Tissues (Posterior)

```
ortho2(robust_window(ss))
```

FSL BET Results not Satisfactory

```
ortho2(rt1, ss > 0, col.y = red0.5)
```

Attempt 2: Bias Correct before BET (recommended)

Before doing skull-stripping/brain extraction, we would do bias correction:

```
library(extrantsr)  
bc_img = bias_correct(file = t1, correction = "N4")
```

```
bc_bet = fslbet(bc_img); ortho2(bc_img, bc_bet > 0, col.y = red0.5)
```

MALF for Skull Stripping

Figure from Multi-Atlas Skull Stripping method paper (Doshi et al. 2013):

- Register templates to an image using the T1 for that subject
- Apply transformation to the label/mask
- Average each voxel over all templates
 - there are “smarter” (e.g. weighted) ways

MALF - use `extrantsr::malf`

- Function requires arguments: `template.images` (T1-weighted images in this case) and `template.structs` (labels/structures/masks, brain masks here)
- We will use the `extrantsr::malf` function
 - Performs non-linear registration using Symmetric Normalization (S_{yN}) (Avants et al. 2008), a form of diffeomorphic registration:
 - combines the template structures

```
library(malf.templates) # load the data package
library(extrantsr)
timgs = mass_images(n_templates = 5) # let's register 5 templates
ss = extrantsr::malf(
  infile = bc_img,
  template.images = timgs$images,
  template.structs = timgs$masks,
  keep_images = FALSE # don't keep the registered images
)
mask = ss > 0
```

MALF performs well

```
mask = readnii("training01_01_mprage_mask.nii.gz") # already computed
```

```
ortho2(bc_img, mask, col.y = red0.5)
```

Conclusions from the MS data

- FSL BET can perform brain extraction (additional ex shows when it works)
 - It did not work sufficiently here
 - There are options you can change for performance
- Bias-correction before brain extraction is a good idea
 - Especially if the method depends on intensities
 - Didn't change the results here
- MALF/MASS is a good option, but needs templates and is computationally expensive
 - weighted templates or local weighting is done in other software (not discussed)

Extra Slides are showing additional BET options

Additional Example

FSL BET did not work in the previous data set. It works in many cases, though. We will look at a subject from the kirby21 dataset (Landman et al. 2011).

```
library(kirby21.t1)
t1_fname = get_t1_filenames()[1]
t1 = readnii(t1_fname)
```

T1 image has the neck!

```
ortho2(robust_window(t1))
```

Neck messes up BET

```
ss = fslbet(infile = t1_fname); ortho2(robust_window(ss))
```

Recommend to Bias Correct first: not fixed

```
bc_img = bias_correct(t1, correction = "N4");  
bc_bet = fslbet(bc_img)  
ortho2(robust_window(t1), bc_bet > 0, col.y = red0.5)
```

BET with neck removal

We use the modification of BET in `extrantsr`, which is called through `fslbet_robust`.
`fslbet_robust`:

- bias correct image
- remove neck (`double_remove_neck` performs 2 registration steps, more robust than one (which is the default).)
- run BET
- estimate center of gravity (COG)
- run BET again with new COG

fslbet_robust syntax

```
ss = extrantsr::fslbet_robust(  
  t1,  
  remover = "double_remove_neck",  
  correct = TRUE,  
  correction = "N4",  
  recog = TRUE)
```

BET with neck removal - works well!

ortho2 (ss)

Conclusions

- Brain extraction allows you to analyze the brain only
 - Important for tissue segmentation/registration
- BET may work (look at your data!)
 - Should bias correct first
 - May need to remove neck
 - High values may affect results - may need to remove/Winsorize them
